The basal vein is not truly a deep vein, rather being a superficial vein at the base of the brain. It is considered deep in surgical literature since it is quite deep as far as the surgeon is concerned and, for example, correlates with a higher degree of morbidity when involved in surgical treatment of AVMs. Generally, the Townes or an even more steep craniocaudal view is a good idea for visualizing the posterior fossa veins. It has the advantages of elongating the basal vein, and projecting the brainstem structures inferior to the torcula / transverse sinuses, and therefore without undue superimposition.
